F# Cheatsheet

Comments

Block comments are placed between (* and *). Line comments start from // and continue until the end of the line.

```
(* This is block comment *)
// And this is line comment
```

XML doc comments come after /// allowing us to use XML tags to generate documentation.

```
/// Double-backticks are placed between a pair of ''
let ''1 + 1 should be equal to 2''() =
    1 + 1 = 2
```

Strings

In F# string is the alias for System.String type.

```
/// Create a string using concatenation operator
let hello = "Hello" + " World"
```

Use *verbatim strings* preceded by @ symbol to avoid escaping control characters (except escaping " by "").

```
let verbatimXml = 0"<book title=""Paradise Lost"">"
```

We don't even have to escape " with triple-quoted strings in F# 3.0.

```
let tripleXml = """<book title="Paradise Lost">"""
```

 $Backslash\ strings$ indent string contents by stripping leading spaces.

```
let poem =
   "The lesser world was daubed\n\
   By a colorist of modest skill\n\
   A master limned you in the finest inks\n\
   And with a fresh-cut quill."
```

Basic Types and Literals

Most of numeric types have associated suffixes e.g. uy for unsigned 8-bit integers and L for signed 64-bit integer.

```
let b, i, 1 = 86uy, 86, 86L
// val 1 : int64 = 86L
// val i : int = 86
// val b : byte = 86uy
```

Other common examples are F or f for 32-bit floating-point numbers, M or m for decimals and I for big integers.

```
let s, f, d, bi = 4.14F, 4.14, 0.7833M, 9999I
// val s : float32 = 4.14f
// val f : float = 4.14
// val d : decimal = 0.7833M
// val bi : System.Numerics.BigInteger = 9999
```

See Literals (MSDN) for complete reference.

Arrays, Lists and Sequences

The same list [1; 3; 5; 7; 9] or array [| 1; 3; 5; 7; 9 |] can be generated in various ways.

• Using range operator ...

```
let xs = [1..2..9]
```

• Using list or array comprehension

```
let ys = [| for i in 0..4 \rightarrow 2 * i + 1 |]
```

• Using init function

```
let zs = List.init 5 (fun i \rightarrow 2 * i + 1)
```

Lists and arrays have comprehensive sets of high-order functions for manipulation.

• fold starts from the left of the list (or array) and foldBack does the opposite

• reduce doesn't require an initial accumulator

```
let last xs = List.reduce (fun acc x -> x) xs
```

• map an array by squaring all elements

```
let ys' = Array.map (fun x -> x * x) [| 1..10 |]
```

• iterate through a list and produce side effects

```
List.iter (fun x -> printfn "%i" x) [ 0..9 ]
```

All the operations above are also available for sequences. The added values of sequences are laziness and uniform treatments for all collections implementing IEnumerable<'T>.

Pattern Matching

Pattern matching is often facilitated through match keyword.

```
let rec fib n =
   match n with
   | 0 -> 0
   | 1 -> 1
   | _ -> fib (n - 1) + fib (n - 2)
```

In order to match sophisticated inputs, one can use when to create filters or guards on patterns:

```
let sign x =
   match x with
   | 0 -> 0
   | x when x < 0 -> -1
   | x -> 1
```

Pattern matching can be done directly on arguments:

```
let fst (x, _) = x
```

or done implicitly via function keyword:

For more complete reference see Pattern Matching (MSDN).

Function Composition and Pipelining

Tuples and Records

Discriminated Unions

Classes and Inheritance

This example is a basic class with (1) local let bindings, (2) properties, (3) methods, and (4) static members.

```
type Vector(x : float, y : float) =
  let mag = sqrt(x * x + y * y) // (1)
  member this.X = x // (2)
  member this.Y = y
  member this.Mag = mag
  member this.Scale(s) = // (3)
     Vector(x * s, y * s)
  static member (+) (a : Vector, b : Vector) = // (4)
     Vector(a.X + b.X, a.Y + b.Y)
```

Call a base class from a derived one.

```
type Animal() =
   member __.Rest() = ()

type Dog() =
   inherit Animal()
   member __.Run() =
       base.Rest()
```

Upcasting is denoted by :> operator.

```
let dog = Dog()
let animal = dog :> Animal
```

Dynamic casting (:?>) might throw an exception if the cast doesn't succeed at runtime.

```
let probablyADog = animal :?> Dog
```

Interfaces and Object Expressions

Declare IVector interface and implement it in Vector'.

Another way of implementing interfaces is to use $object\ expressions.$

```
type ICustomer =
   abstract Name : string
   abstract Age : int

let createCustomer name age =
   { new ICustomer with
       member __.Name = name
       member __.Age = age }
```

Namespaces and Modules

Async Workflows

Active Patterns

Complete active patterns:

```
let (|Even|Odd|) i =
   if i % 2 = 0 then Even else Odd

let testNumber i =
   match i with
   | Even -> printfn "%d is even" i
   | Odd -> printfn "%d is odd" i
```

Parameterized active patterns:

```
let (|DivisibleBy|_|) by n =
   if n % by = 0 then Some DivisibleBy else None
let fizzBuzz = function
   | DivisibleBy 3 & DivisibleBy 5 -> "FizzBuzz"
   | DivisibleBy 3 -> "Fizz"
   | DivisibleBy 5 -> "Buzz"
   | _ -> ""
```

Partial active patterns have the same syntax as the parameterized one above but their active recognizers accept only one argument.

Compiler Directives

Load another F# source file into FSI.

```
#load "../lib/StringParsing.fs"
```

Reference an .NET assembly (/ symbol is recommended for Mono compatibility).

```
#r "../lib/FSharp.Markdown.dll"
```

Include a directory in assembly search paths.

```
#I "../lib"
#r "FSharp.Markdown.dll"
```

Other important directives are conditional execution in FSI (INTERACTIVE) and querying current directory (__SOURCE_DIRECTORY__).

```
#if INTERACTIVE
let path = __SOURCE_DIRECTORY__ + "../lib"
#else
let path = "../../../lib"
#endif
```
